LSST Event Broker

Team 8

Christopher Wells, Christian Sumano, Christian Van Cleef, Clare Volta, Faizon Zaman

Our Project

To build an "Event Broker" for the Large Synoptic Survey Telescope.

This broker should receive and process data on transients from the LSST.

The goal is to classify these transients through a series of binary classifiers.

Use Cases

Help researchers examine transient data from the LSST

We aimed for a high level of abstraction so that researchers could simply "plug in" whichever rules they would like to use to classify transients.

Our framework can be used by anyone interested in learning about astrophysical phenomena

Domain Research

Building an Event Broker required knowledge of how astrophysical events are classified by astronomers.

We were fortunate to have assistance by our domain experts, Professor Kanbur and Professor Ashish Mahabal of Caltech

We learned of the many factors that govern star classification:

-- Time series frequency

-- Light magnitude

-- Periodicity

-- Slope

-- Color

...and more

Prototype

First step was to set up a prototype

Created a working binary classifier

Created our own dummy data to test the output

Ex. returning a single observation data

Classify the data based on if the slope exceeds a particular margin of error

Incredibly accurate in classifying the correct transient

Framework Design

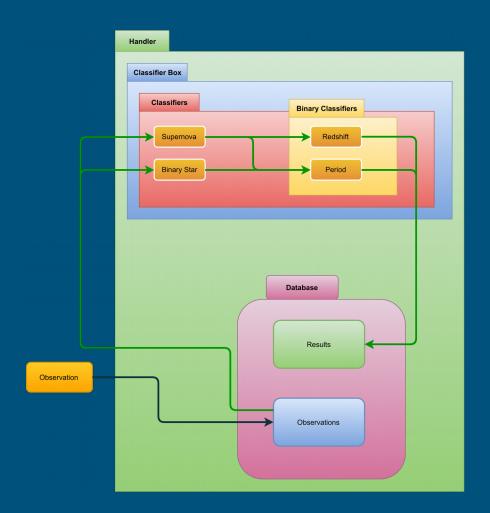

Focuses on allowing the researcher to specify everything

Made up of composable pieces

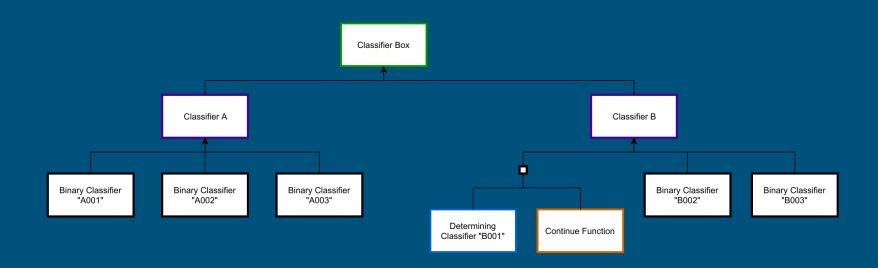

Handles input/output separate from calculations

Allows for parallelism and concurrency

Enables easy testing of the framework

Data Flow

Classifier Box Construction

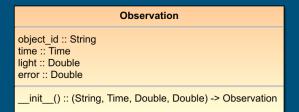

Framework Implementation

Implemented in Python using an OOP approach

Included a Handler for MySQL

Unit tests for the non-input/output components

Used Conda for library packaging

Result object_id :: String time :: Time classifier_name :: String probability :: Double (String, Time, String, Double)

ContinueFunction

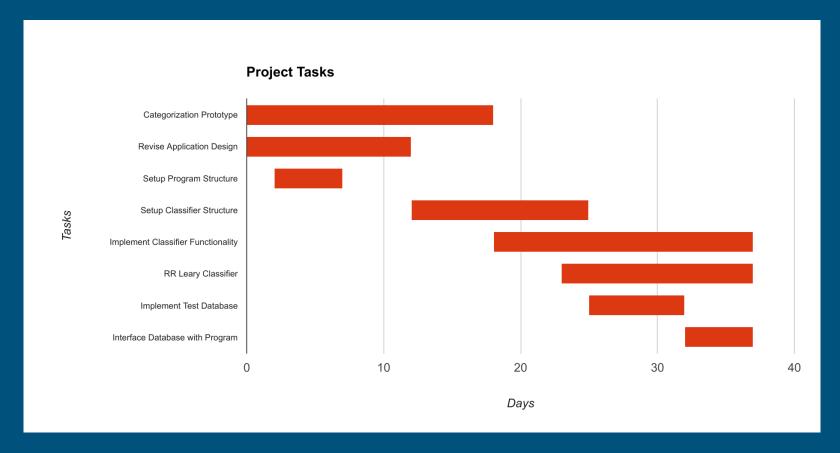

Result -> Boolean

ClassifyingFunction

[Observation] -> Result

ClassifierBox classifiers :: [Classifier] add_classifier() :: Classifier -> Void run() :: [Observation] -> [[Result]] Classifier determining_classifier :: BinaryClassifier continue function :: ContinueFunction binary classifiers :: [BinaryClassifier] set determining classifier():: (BinaryClassifier, ContinueFunction) -> Void add binary classifier():: BinaryClassifier -> Void run() :: [Observation] -> [Result] **BinaryClassifier** name :: String classifying_function :: ClassifyingFunction init ():: (String, ClassifyingFunction) -> BinaryClassifier run() :: [Observation] -> Result
